

Software Design

Audible-Plot

Daniel Birket & Lawrence Perez

April 2, 2023

Abstract

This document describes the software design for audible-plot.

1 Class Pitch

This class represents a pitch or frequency and converts between three pitch and frequency formats.

1.1 Instance Variables

Instances of this class have the following variables:

- `_midi`: The pitch as a float MIDI number, with the int MIDI number expressed as the integer portion and the 'bend' between the notes as the float portion after the decimal point.

There are no instance variables for `freq` and `note`. These are derived from `_midi` by the getter functions.

1.2 Properties

- Integer MIDI note number, 0 to 127
- String note name and octave: "C0" to "C9" including sharps and flats like "F#4" and "Eb3"
- Frequency, in Hertz

The internal representation of the pitch will be a MIDI number between 12 and 127, stored as a 'float' instead of 'integer'. The class must extend the class "object", not "float".

The frequency corresponding to any pitch can be computed with the formula:

$$f = 440 * 2^{(m-69)/12}$$

Where:

- `f`: frequency in hertz
- `m`: MIDI note number, as a float

or in python:

$$\text{freq} = 440.0 * 2.0^{((\text{midi} - 69.0)/12)}$$

In the other direction, the float midi note may be calculated by inverting the same equation:

$$m = 12 * \log_2(f/440) + 69$$

or in python:

```
midi = 12.0 * math.log2(freq / 440.0) + 69.0
```

When converting from a string to a MIDI note, the string should be of the format "C0" or "C#0", with the capital note letter name as the first character, the digit of the octave as the last digit and an optional "#", "" (Unicode "MUSIC SHARP SIGN"), or "+" (PLUS), or a "b", "" (Unicode "MUSIC FLAT SIGN"), or "-" (HYPHEN) character between them.

The octave digit must be 0 to 9. Note that some of octave 0 is below the range of human hearing. The base MIDI number of each octave is:

Octave	MIDI
0	12
1	24
2	36
3	48
4	60
5	72
6	84
7	96
8	108
9	120

The base MIDI note of each octave may be computed as:

$$base = 12 * (octave + 1)$$

The octave of a MIDI note may be computed as:

$$octave = int((midi - 12)/12)$$

This formula produces:

MIDI	Octave
12	0
23	0
24	1
35	1
36	2
119	8
120	9

The note letter must be capital A to G. These notes map to an MIDI note offset from the base of the octave as follows:

Note	Offset
C	0
D	2
E	4
F	5
G	7
A	9
B	11

The accidental (sharp or flat) must be one of #, , or + for sharp or b, , or - for flat. These characters add or subtract one from the MIDI note number. Double sharps and double flats, if implemented, add or subtract 2 midi notes. Unusual musical combinations, like "E#4" or "Cb4", which are the same as "F4" and "B3", respectively, are permitted.

The MIDI number is the sum of the octave base, the note offset and the +1 or -1 for a sharp or flat, if any

If the string is not of this format, then the conversion should check if the string is a valid integer or float number in the range greater than or equal to 12 and less than 128 and interpret a number in that range as a float MIDI number.

If the string is empty, or the integer is 0, or the float is 0.0, the pitch should initialize to "A4", a 440 Hz 'A' note.

If the string or integer or float is negative, it should raise a ValueError.

Finally, if the string is a valid integer or float greater than or equal to 128 and less than or equal to 22000, it should interpret the value as a frequency.

If the initializer is already an integer or float, it should perform the same range checks.

If the string is neither a valid note name or a number in one of the valid ranges for a MIDI note or an audible frequency, it should raise a ValueError.

If the initializer is not a string, integer or float, note tuple, or another Pitch, it should raise a TypeError.

Except for the dunder init initializer, which detects the format of the pitch, Pitch should provide a property() interface to note, midi and freq fields, with getter and setter methods and doc strings.

When converting from a float MIDI number to a note string, the program will return a 2-item tuple. The first item of the tuple must be a note string with note letter, optional sharp sign (using the shift-3 sharp not the unicode "MUSIC SHARP SIGN", and the octave digit. The note string represents the integer part of the float MIDI number. The second item of the tuple must be the fractional part of the MIDI number, a float number greater than or equal to 0.0 and less than 1.0.

The dunder init initializer should also accept this tuple.

1.3 Methods

In addition to property getters and setters, the class has the following methods:

- `__init__` : Initializes a pitch from one of several formats.
- `__str__` : Returns a string of the pitch and bend, if any.

- `__repr__`: Returns a representation of the Pitch

1.4 Interface

The class Pitch must have the following interface:

```
"""Temporary module to document the Pitch class"""
from typing import Any

class Pitch(object):

    # Getter and Setter of midi (same as internal _midi)
    @property
    def midi(self) -> float:
        "float MIDI number of pitch."
        return self._midi

    @midi.setter
    def midi(self, m: float) -> None:
        assert isinstance(m, int) or isinstance(m, float)
        # assert valid 12 to 127 midi number here
        self._midi = float(m)

    @midi.deleter
    def midi(self) -> None:
        self._midi = 69.0 # "A4", 440 Hz 'A'

    # Getter and Setter of frequency
    @property
    def freq(self) -> float:
        "float frequency of pitch in hertz."
        return 0.0

    @freq.setter
    def freq(self, f: float) -> None:
        assert isinstance(f, int) or isinstance(f, float)
        # assert audible frequency range here
        self._midi = 0.0

    @freq.deleter
    def freq(self) -> None:
        del self.midi

    # Getter and Setter of note string
    @property
    def note(self) -> tuple:
        "pitch as tuple of note string and fractional note."
```

```

        return ("A4", 0.0)

@note.setter
def note(self, n) -> None:
    if isinstance(n, tuple):
        note_str, note_bend = n # unpack tuple
    elif isinstance(n, str):
        note_str = n
        note_bend = 0.0
    assert isinstance(note_str, str), "Note string must be a string like 'A4'."
    assert isinstance(note_bend, float), "Note bend must be a float like 0.0."
    assert 0.0 <= note_bend < 1.0, "Note bend must 0.0 or between 0.0 and 1.0."

    self._midi = 0.0

@note.deleter
def note(self) -> None:
    del self.midi

def __init__(self, value: Any = None) -> None:
    pass
    if isinstance(value, tuple) or isinstance(value, str):
        self.note = value
    elif isinstance(value, float) or isinstance(value, int):
        if value < 128.0:
            self.midi = value
        else:
            self.freq = value
    else:
        raise TypeError("value must be tuple, string, float or int.")

    # if isinstance(value, int) or isinstance(value, float)
    midi = 0

def __str__(self) -> str:
    """Return string of note and bend."""
    n = self.note
    return n[0] + "+" + str(n[1])

def __repr__(self) -> str:
    """Return representation of Pitch."""
    return type(self).__name__ + "(" + self.midi + ")"

```

2 Class PlotData

This class describes the data to be plotted (either visually or audibly).

2.1 Instance Variables

Instances of this class have the following variables:

- `_points`: a NumPy ndarray of the points, with the x values in the first position.
- `_xrange`: The min and max of the x coordinates of the points
- `_yrange`: The min and max of the y coordinates of the points
- `_xlabel`: The x-axis label
- `_ylabel`: The y-axis label
- `_xdescr`: A verbose description of the x-data
- `_ydescr`: A verbose description of the y-data.
- `_line_labels`: A list of strings labeling the lines, one for each line.
- `_line_descrs`: A list of strings describing the lines, one for each line.
- `_title`: The title of the plot
- `_description`: A verbose description of the plot

2.2 Properties

This class has the following properties, with automatic getters and setters.

- `points`: an m by n matrix (numpy ndarray) of floats giving the horizontal x-axis coordinates in the $m = 0$ column and the vertical y-axis coordinates of the points to plot for m-1 lines in the remaining columns.
 - the number of horizontal x coordinates, n, is expected to be between 2 and 100
 - the number of sets of vertical y coordinates (ie. functions) is expected to be between 1 and 9, so 'm', which includes the x coordinates, will be between 2 and 10.
 - the array is stored as a vector (list) of points, where each point is a vector of at least two floats: (x, y1). 'points[0]' is the first set of points at the x-position points[0,0].
- `xrange`: a tuple of two floats (min, max). The horizontal range to plot. If set to (0,0) or min = max, the range will be calculated from the points array. If (min > max), they will be swapped.
- `yrange`: a type of two floats (min, max). The vertical range to plot. If set to (0,0) or min = max, the range will be calculated from the points array. If (min > max), they will be swapped.
- `xlabel`, `ylabel`: a (short) string used to label the x and y axis respectively.
- `xdescr`, `ydescr`: a (verbose) string describing the x and y axis respectively. Defaults to the respective label.
- `line_labels`: a list of (short) strings labeling the lines. Defaults to "Line 1", "Line 2", etc.
- `line_descrs`: a list of (verbose) strings describing the lines: Defaults to the respective line_labels.
- `title`: a (short) string used to title the entire plot.

- description: a (verbose) string describing the entire plot. Defaults to the title.

2.3 Methods

In addition to property getters and setters, the class has the following methods:

- `autorange()`: set xrange based on the points.
- `autoyrange()`: set yrange based on the points.
- `xsize()`: get the number of points horizontally
- `ysize()`: get the number of functions vertically

2.4 Interface

The class must have the following interface:

```
"""Temporary module to document the PlotData class"""
import numpy as np

class PlotData(object):
    """Class to hold data to be plotted and associated descriptors."""

    @property
    def points(self) -> np.ndarray:
        """Numpy n-dimension array of points. X-values first."""
        return self._points

    @points.setter
    def points(self, p: np.ndarray) -> None:
        self._points = p

    @points.deleter
    def points(self) -> None:
        self._points = np.ndarray([[0, 0], [1, 1]])

    @property
    def xrange(self) -> tuple[float, float]:
        """Min and Max of the x-values."""
        return self._xrange

    @xrange.setter
    def xrange(self, xr: tuple[float, float]):
        """Set the min and max of the x-values. If min = max, then
        perform autorange. If min > max, then swap them."""
        self._xrange = xr

    @xrange.deleter
    def xrange(self) -> None:
```

```

        self.xrange = (0, 0)

    @property
    def yrange(self) -> tuple[float, float]:
        """Min and Max of the y-values, for all functions."""
        return self._yrange

    @yrange.setter
    def yrange(self, yr: tuple[float, float]):
        """Set the min and max of the y-values. If min = max, then
        perform autoyrange. If min > max, then swap them."""
        self._yrange = yr

    @yrange.deleter
    def yrange(self) -> None:
        self.yrange = (0, 0)

    @property
    def xlabel(self) -> str:
        """Short label of x-axis"""
        return self._xlabel

    @xlabel.setter
    def xlabel(self, xl: str):
        self._xlabel = xl

    @xlabel.deleter
    def xlabel(self) -> None:
        self._xlabel = ""

    @property
    def ylabel(self) -> str:
        """Short label of y-axis"""
        return self._ylabel

    @ylabel.setter
    def ylabel(self, yl: str):

    self.ylabel = "y"
    self.xdescr = "x-data"

```

```

self.ydescr = "y-data"
self.title = "X-Y Plot"
self.description = ""

```

3 Class PlotVisual

This class describes and creates the desired visual plot of the data described by the PlotData class.

3.1 Instance Variables

Instances of this class have the following variables:

- `_format`: one of "png", "gif", or "jpeg"
- `_output`: name of the gpl and output file, less the file extension
- `_size`: tuple of (xpixels, ypixels)

3.2 Properties

This class has the following properties, with automatic getters and setters.

- `format`: format of the graphics file. One of "png", "jpeg", "gif" or "svg". The default is "png". If set to another string, the default will be used. The format is used to set the format of the output of gnuplot and to set the output filename extension.
- `output`: name of the graphics file and the gpl file. If nothing is specified, the title of the plotdata will be used. The filetype will be appended to this string to set the output filename. 'gpl' is appended to create the gpl filename. May not contain "gpl" or one of the format strings.
- `size`: the x and y size of the graphic in pixels. A tuple (xpixels, ypixels). The default is (640, 480)

3.3 Methods

In addition to property getters and setters, the class has the following methods:

- `__init__(plotdata: PlotData)`
- `out_filename()`: Complete output filename assembled from 'output' and 'format'.
- `gpl_filename()`: Complete gnuplot filename assembled from 'output' and ".gpl"
- `write_gpl()`: Write the 'gnuplot' command gpl file (with embedded data block)
- `plot_gpl()`: Plot the gpl command file with 'gnuplot'.

3.4 Interface

The class must have the following interface:

```

"""Temporary Module to document the PlotVisual class."""

class PlotVisual(object):

```

pass
